Apple has through the performance objectives of New product design and development, technology and Quality Management have seen a very significant effect on their ability to achive the performance objectives of: Cost, ~~dependability~~, flexibility, dependability, quality and speed. This can be measured by the achievement of their respective quantitative values, as well as the achievement of the business goals of profit maximisation and increased market share. However, long-term success has also been exposed to short-term decline and the failure to helfill this criteria.

New Product development and design is the strategy of releasing new or different products on a consistent bass in order to maintain presence and relevance in the market. Apple does this through releasing products of their main sub-sections (iPhone, iPad, Apple Watch etc.) on a yearly basis. This strategy targets quality, cost and dependability. Apple's strategic use of New product design and development achieves success regularly of the performance objective of quality, as their yearly renditions of their products is seen to link to the level of defects that are and returns/faults in their products.

Apple is world renowned for the quality of their goods, with a long-term average for defects in their various smartphone renditions being 7% of all sold products. However, in 2014, the release of the iPhone 6 saw a jump to 22% of all goods sold being defected due to the new design not yet having been perfected, with the thin aluminium frame being easy to bend. Apple then used the strategy of New product development to remedy this, with the following release showing a defect decrease to only 6%. Apple's use of this strategy also targets cost as a performance objective. Apple usually follows a trend where after the release of a new design for their products, the release in the next year is a development on this to make improvements in production and quality. Thus the Apple saw a reduction of the price per unit of their phones from $229.80 in 2014 for their iPhone 6 to a only $200 per unit for the iPhone 6s, despite the increase in quality. This is caused by global sourcing and economies of scale. Apple also utilises the strategy of New product design and development to increase dependability in their products. This is also seen in the decrease in defects through the renditions, with defects for the 2017 iPhone X only being 3% of all sold goods.

Quality, cost and dependability have all been achieved by Apple through the use of New product design and development, and this can also be seen in the increase in Profit, from an annual 45.6 billion USD for 2016 to 46.7 billion USD in 2017, as well as a record high market share of 51% for all smartphones in the first quarter of 2018.

*, quality.

The strategy of technology is the use of both leading edge and established technology within a business's production and innovation of goods to an effect performance objectives positively. Thus in Apple, this is seen through the performance of objectives of speed, flexibility* and cost. Apple has used both leading edge and existing technology for their goods since the company's inception, however their focus of technology strategy remains within their production process. Technology allows Apple to achieve speed and flexibility through the use of leading edge technology in their manufacturing plants to decrease the decrease the time of production per unit, as well as to be able to respond to variations/fluctuations of demand in the market for their goods. In 2017, after the announcement

E

their iPhone X. The demand early was very significant, and meant Apple was forced to delay orders after the original wave of units for over 2 months. Many analysts predicted at the time that this delay would be closer to 6 months. However Apple utilized leading edge technology in their manufacturing plants to ramp the number of units per week of the iPhone X from 100,000 units per week to almost 2 million units per week to meet the demands of the market, and shorten delays. This significant increase also leads to the achievement of cost, as Apple were required to purchase more inputs, thus creating a larger economies of scale and decreasing the per unit cost of production. ~~Quality~~ Dependability also ~~Reliability~~ achieved through technology as the goods produced using the latest innovations in the industry, as well as tested, established technology, like the iPhone X, will increase consumer's trust ~~and~~ and willingness to buy Apple's products. Through speed, flexibility, dependability and cost, Apple has achieved performance objectives through using technology strategies in order to achieve Profit and market share increases.

Apple uses Quality Management as a Quality management is the strategy used to limit defects in a business' production process, thus decreasing the waste of goods which leads to a decrease in profitability. Through the performance objectives of Dependability, Quality and speed are effected through Quality management, and its three components; Quality assurance, Quality control and Quality improvement. Apple uses Quality management throughout their manufacturing plants in order to create systemic levels of quality in order to maximise profits, as well as ensuring consumers of the highest grade of product. Dep Quality assurance is the process of having frequent checkpoints of a goods production, and collecting data on the rate of faulty products. This allows Apple to identify the source of the issue and to directly target it rather than having to re-evaluate the entire production process. Apple, through Foxconn, their outsourced manufacturer, returned 40% of all Iphone X displays before they were used in the early stages of production due to defects from the supplies of Samsung. This stopped many transformed products reaching the market with faulty screens. Quality Control is where a business puts in place regulations and directions of production in order to

stop the inflow of defects in their products. Apple uses this in order to prevent finished goods with defects ~~in~~ found reaching the market of consumers. Thus, therefore both increases quality and dependability of Apple in the minds of consumers, encouraging them to purchase more products in the future due to the reputation. However, ~~this~~ an unsuccessful example of this Quality Control not occurring is of ~~the~~ Apple's largest competitors in the personal technology market, Samsung. Samsung, with the release of their Galaxy Note 7, endangered consumers due to the space the battery was placed in the phones being to small, leaving the phones liable to explosion in particular circumstances. Samsung then replaced the defects with products that had the same issue, thus resulting in the recall of millions of devices as well as the tarnishing of the brand's reputation. Quality Improvement is where a business instills a protocol in which targets sustained long term improvement in the quality of their goods. This is seen in Apple with their record low defect rate of 3% in 2017, with a projected low of 1.5% for the iPhone Xs and Xs Max in 2018. Samsung has also

Additional writing space on back page.

experienced thus through their improvement in their note series that are no longer liable to explode and have a defect rate of 4.5% for the Galaxy note 9 & 10. However, Quality management in Apple does come at an expense of speed, which is slowed due to the extensive checking process. Apple and Samsung have seen varying levels of success through quality management, resulting in increase in Profit and market share for Apple long-term and short-term decline for Samsung.

Apple has utilised New product design and development, technology and Quality Management to have a very significant effect on the performance objectives, and in turn, achieving business goals of profit and market share.
